

Package: mlma (via r-universe)

August 24, 2024

Type Package

Title Multilevel Mediation Analysis

Version 6.3-1

Date 2023-08-29

Author Qingzhao Yu, Bin Li

Maintainer Qingzhao Yu <qyu@lsuhsc.edu>

Depends R (>= 2.14.1), lme4, car, abind, coxme, gplots

Imports survival, splines

Suggests knitr, rmarkdown

VignetteBuilder knitr

Encoding UTF-8

Description Do multilevel mediation analysis with generalized additive multilevel models. The analysis method is described in Yu and Li (2020), "Third-Variable Effect Analysis with Multilevel Additive Models", PLoS ONE 15(10): e0241072.

mlma-package	<i>Multilevel Mediation Analysis</i>
--------------	--------------------------------------

Description

The package is used to do mediation analysis with generalized multilevel models.

Details

"[data.org](#)" is used to transform the variables and organize the predictor, mediators and outcome into the format that are ready to be used for multilevel mediation analysis. "`mlma`" is for multilevel mediation analysis on the original data set. "`boot.mlma`" is a combined function that organized data set, do multilevel mediation analysis on original data sets and bootstrapping samples.

The multilevel mediation is based on the following linear multilevel additive models:

$$Y_{ij} = u_{0j}^Y(X_{.j}, \mathbf{M}_{.j}, \mathbf{Z}_{.j}) + \beta_{10}^Y \mathbf{f}_{10}^Y(X_{ij} - X_{.j}) + \sum_{k=1}^K \beta_{20k}^Y \mathbf{f}_{20k}^Y(M_{ijk} - M_{.jk}) + \beta_{30}^Y \mathbf{f}_{30}^Y(\mathbf{Z}_{ij} - \mathbf{Z}_{.j}) + r_{ij}^Y,$$

where

$$u_{0j}^Y(X_{.j}, \mathbf{M}_{.j}, \mathbf{Z}_{.j}) = c_{00}^Y + \beta_{01}^Y \mathbf{f}_{01}^Y(X_{.j}) + \sum_{k=1}^K \beta_{02k}^Y \mathbf{f}_{02k}^Y(M_{.jk}) + \beta_{03}^Y \mathbf{f}_{03}^Y(\mathbf{Z}_{.j}) + r_{0j}^Y.$$

For $k = 1, \dots, K$,

$$M_{.jk} = u_{0jk}^M(X_{.j}) + \beta_{10k}^M \mathbf{f}_{10k}^M(X_{ij} - X_{.j}) + r_{ijk}^M,$$

$$u_{0jk}^M(X_{.j}) = c_{00k}^M + \beta_{01k}^M \mathbf{f}_{01k}^M(X_{.j}) + r_{0jk}^M.$$

If for some k , M_k is level 2 variable,

$$M_{.jk} = c_{00k}^M + \beta_{01k}^{M^T} \mathbf{f}_{01k}^{M2}(X_{.j}) + r_{0jk}^M.$$

Note that in the models, $\mathbf{f}(\cdot) = (f_1(\cdot), f_2(\cdot), \dots, f_l(\cdot))^T$ is a set of l transformation functions on \cdot , with the corresponding linear coefficients vector $\beta = (\beta_1, \beta_2, \dots, \beta_l)^T$. \mathbf{f} and l are known for model fitting. l may be different with \mathbf{f} of different sub- and super-scripts.

boot.mlma

Bootstrap Method for Inference on Multilevel Mediation Analysis

Description

Bootstrap samples are selected from the original data set. The bootstrap sample has the same number of groups and in each group, the same number of observations as in the original data set. Based on each bootstrap sample, a multilevel mediation analysis is done and the results saved to make inferences on the total, direct and indirect effects.

Usage

```
boot.mlma(y, data1=NULL, x=data1$parameter$x, m=data1$parameter$m,
  levelx=data1$parameter$levelx, levely=data1$parameter$levely,
  xref=NULL, yref=NULL,
  l1=data1$parameter$l1, l2=data1$parameter$l2,
  c1=data1$parameter$c1, #levelx is the level of x
  c1r=data1$parameter$c1r, c2=data1$parameter$c2,
  c2r=data1$parameter$c2r, level=data1$parameter$level,
  weight=rep(1, nrow(as.matrix(x))),
  random="(1|level)", random.m1=NULL, intercept=TRUE,
  family1=NULL, familym=vector("list", ncol(m)),
  covariates=NULL, cy1=NULL, cy2=NULL, cm=NULL,
```

```

joint=NULL, f01y=data1$parameter$f01y,
f10y=data1$parameter$f10y, f02ky=data1$parameter$f02ky,
f20ky=data1$parameter$f20ky, f01km1=data1$parameter$f01km1,
f01km2=data1$parameter$f01km2, f10km=data1$parameter$f10km,
data2=NULL, x.new=NULL, m.new=m, level.new=level,
weight.new=NULL, covariates.new=covariates, boot=100, echo=TRUE,
plot.it=TRUE, cov.mat=FALSE)

```

Arguments

y	the vector of the outcome variable.
data1	the results from data.org. If data1=NULL, needs to set up x, m, levelx, xref, l1, l2, c1, c2, c2r, f01y, f10y, f02ky, f20ky, f01km1, f01km2, f10km ...
x	the vector of the predictive variable.
m	the mediators. The program will identify the levels and types of each mediator if not specified by l1, l2, c1, or c2. A mediator is identified as categorical if the mediator is a factor, a character, or has only two unique values.
levelx	the level of x (1 or 2). If it is not given, levelx will be decided by x.
levely	the level of y (1 or 2). If it is not given, levely will be decided by y.
xref	the reference group of x if it is binary. By default it will be the first level of x.
yref	the reference group of y if it is binary. By default it will be the first level of y.
l1	the column numbers of level 1 continuous mediators in m.
l2	the column numbers of level 2 continuous mediators in m.
c1	the column numbers of level 1 categorical mediators in m.
c1r	the reference groups of categorical mediators specified by c1.
c2	the column numbers of level 2 categorical mediators in m.
c2r	the reference groups of categorical mediators specified by c2.
f01y, f10y, f02ky, f20ky, f01km1, f01km2, f10km	the transformation functions as describe in the function " data.org ". Need these arguments only when org.data=T.
level	a vector that record the group number for each observation.
weight	the weight of cases in groups.
random	the random effect part for the full model. random = "(1 level)" by default.
random.m1	the random effect part for model explaining the mediators. All other random effects are random = "(1 level)" if not specified here.
intercept	True if fit an intercept to models, by default.
family1	the glm family for the response variable y. If it is null, will be binomial with logic link for binary y and gaussian with identity link for continuous y.
familym	a list of length ncol(m), each item gives the glm family for the corresponding column of m. If an item is null, the family will be binomial with logic link for binary m and gaussian with identity link for continuous m.
boot	the number of bootstrapping samples.

covariates	the covariates matrix to explain the outcome, y, and/or the mediators, m.
cy1	the column numbers of covariates that are level 1 and used to explain y.
cy2	the column numbers of covariates that are level 2 and used to explain y.
cm	the column numbers of covariates that are used to explain m. cm[[1]] gives the mediators (in l1, c1, l2, or c2) that can be partially explained by covariates. Each of the rest items of the cm list shows the column number(s) in covariates that should be used to explain each mediator listed in cm[[1]] and by that order. For example, joint=list(1,c("m.2","m.4")) means find the joint effects of level 1 mediators m.2 and m.4.
joint	the list of group(s) of mediators whose joint mediation effect is of interests. joint[[1]] list the levels of mediators in each group and by the order of the list. Note that if any mediator in the group is of level 2, the level of the group should be 2.
data2	the results from data.org on x.new, covariates.new, m.new, level.new, and weight.new. If data1=NULL, needs to rerun data.org on the new data. If x.new is also NULL, set data2=data1. The new data is the same as the old data.
x.new, covariates.new, m.new, level.new, weight.new	the settings that we want to make inferences on the mediation effects. If m.new=NULL, generate new mediators from x.new.
echo	print a i when finish the ith bootstrap estimation if echo=T.
plot.it	If true, middle results will be stored for future use to plot confidence intervals.
cov.mat	If true, the result on full dataset include the estimation of variances through normal approximation.

Details

The multilevel mediation is based on the following linear multilevel additive models:

$$Y_{ij} = u_{0j}^Y(X_{.j}, \mathbf{M}_{.j}, \mathbf{Z}_{.j}) + \beta_{10}^Y \mathbf{f}_{10}^Y(X_{ij} - X_{.j}) + \sum_{k=1}^K \beta_{20k}^Y \mathbf{f}_{20k}^Y(M_{ijk} - M_{.jk}) + \beta_{30}^Y \mathbf{f}_{30}^Y(\mathbf{Z}_{ij} - \mathbf{Z}_{.j}) + r_{ij}^Y,$$

where

$$u_{0j}^Y(X_{.j}, \mathbf{M}_{.j}, \mathbf{Z}_{.j}) = c_{00}^Y + \beta_{01}^Y \mathbf{f}_{01}^Y(X_{.j}) + \sum_{k=1}^K \beta_{02k}^Y \mathbf{f}_{02k}^Y(M_{.jk}) + \beta_{03}^Y \mathbf{f}_{03}^Y(\mathbf{Z}_{.j}) + r_{0j}^Y.$$

For $k = 1, \dots, K$,

$$M_{.jk} = u_{0jk}^M(X_{.j}) + \beta_{10k}^M \mathbf{f}_{10k}^M(X_{ij} - X_{.j}) + r_{ijk}^M,$$

$$u_{0jk}^M(X_{.j}) = c_{00k}^M + \beta_{01k}^M \mathbf{f}_{01k}^M(X_{.j}) + r_{0jk}^M.$$

If for some k, M_k is level 2 variable,

$$M_{.jk} = c_{00k}^M + \beta_{01k}^M \mathbf{f}_{01k}^{M2}(X_{.j}) + r_{0jk}^M.$$

Note that in the models, $\mathbf{f}(\cdot) = (f_1(\cdot), f_2(\cdot), \dots, f_l(\cdot))^T$ is a set of l transformation functions on \cdot , with the corresponding linear coefficients vector $\beta = (\beta_1, \beta_2, \dots, \beta_l)^T$. \mathbf{f} and l are known for model fitting. l may be different with \mathbf{f} of different sub- and super-scripts.

Value

Return a "mlma.boot" mode list, which include the following items:

de1	direct effect(s) of level 1 exposure(s). de1 is a matrix of dimension n times boot by nx1, where n is the number of observations, and nx1 is the number of level 1 exposures. boot is the number of bootstrap samples.
de2	direct effect(s) of level 2 exposure(s). de2 is a matrix of dimension n2 times boot by nx2, where n2 is the number of unique levels, and nx2 is the number of level 2 exposures.
ade1	average direct effect(s) of level 1 exposure(s). ade1 is a matrix of dimension boot by nx1.
ade2	average direct effect(s) of level 2 exposure(s). ade2 is a matrix of dimension boot by nx2.
te1	total effect of each level 1 exposure. te1 is a matrix of dimension n times boot by nx1, where n is the number of observations, and nx1 is the number of level 1 exposures.
te2	total effect of each level 2 exposure. te2 is a matrix of dimension n2 times boot by nx2, where n2 is the number of unique levels, and nx2 is the number of level 2 exposures.
ate1	average total effect(s) of level 1 exposure(s). ate1 is a matrix of dimension boot by nx1.
ate2	average total effect(s) of level 2 exposure(s). ate2 is a matrix of dimension boot by nx2.
ie1	level 1 indirect effect from level 1 exposure(s) to level 1 mediator(s) on the outcome. ie1 is an array of dimension (n*boot,nm1,nx1), where nm1 is the number of level 1 mediators.
ie2	level 2 indirect effect from level 2 exposure(s) to level 2 mediator(s) on the outcome. ie2 is an array of dimension (n2*boot,nm2,nx2), where nm2 is the number of level 2 mediators.
ie12	level 2 indirect effect from level 2 exposure(s) to level 1 mediator(s) on the outcome. ie12 is an array of dimension (n2*boot,nm1,nx2).
aie1	level 1 average indirect effect from level 1 exposure(s) to level 1 mediator(s) on the outcome. aie1 is a matrix of dimension (nm1*boot,nx1).
aie2	level 2 average indirect effect from level 2 exposure(s) to level 2 mediator(s) on the outcome. aie2 is a matrix of dimension (nm2*boot,nx2).
aie12	level 2 average indirect effect from level 2 exposure(s) to level 1 mediator(s) on the outcome. aie12 is a matrix of dimension (nm1*boot,nx2).
je1	joint level 1 indirect effect from level 1 exposure(s) to joint level 1 mediators on the outcome. je1 is an array of dimension (n*boot,nj1,nx1), where nj1 is the number of groups of level 1 mediators.
je2	joint level 2 indirect effect from level 2 exposure(s) to joint level 2 mediators on the outcome. je2 is an array of dimension (n2*boot,nj2,nx2), where nj2 is the number of groups of level 2 mediators.

je12	joint level 2 indirect effect from level 2 exposure(s) to joint level 1 mediators on the outcome. je12 is an array of dimension $(n2*boot,nj1,nx2)$.
aje1	average joint level 1 indirect effect from level 1 exposure(s) to joint level 1 mediators on the outcome. aje1 is a matrix of dimension $(nj1*boot,nx1)$.
aje2	average joint level 2 indirect effect from level 2 exposure(s) to joint level 2 mediators on the outcome. je2 is a matrix of dimension $(nj2*boot,nx2)$, where nj2 is the number of oflevel 2 mediators.
aje12	average joint level 2 indirect effect from level 2 exposure(s) to joint level 1 mediators on the outcome. je12 is a matrix of dimension $(nj1*boot,nx2)$.
full	an "mlma" results using the original data set.
xboot	a $n*boot$ vector of the level 1 predictors in all boot bootstrap samples.
xjboot	a $g*boot$ vector of the (aggregated) level 2 predictors in all boot bootstrap samples.
levelx	inherited from the same argument.
level	inherited from the same argument.

Examples

```
data(sim.111)
sim.111$m[,3]=as.factor(sim.111$m[,3])
data2<-data.org(ifelse(sim.111$x>1.9,1,0), m=sim.111$m,
  f10y=list(1,c("x^2","sqrt(x+6)")),
  f20ky=list(2,c("x","x^3")),
  f10km=list(matrix(c(2,1),1),"log(x+2)"), level=sim.111$level)
temp2.boot<-boot.mlma(y=sim.111$y, data1=data2,boot=2, joint=list(1,1:2))
```

```
#can also do the above analysis using the following code
temp2.boot<-boot.mlma(y=ifelse(sim.111$y>4.5,1,0), x=sim.111$x, m=sim.111$m,
  f10y=list(1,c("x^2","sqrt(x+6)")),
  f20ky=list(2,c("x","x^3")),
  f10km=list(matrix(c(2,1),1),"log(x+2)"), level=sim.111$level,boot=2)
```

```
#with a level 2 exposure
data(sim.211)
data1<-data.org(x=ifelse(sim.211$x>2.2,1,0), m=sim.211$m,
  f02ky=list(1,c("x","x^2")),
  f20ky=list(2,c("x","x^3")), f01km2=list(matrix(c(1,1),1),c("x^1.2","x^2.3")),
  f01km1=list(matrix(c(2,1),1),"sqrt(x)+3"), level=sim.211$level)
temp1.boot<-boot.mlma(y=sim.211$y, data1=data1,boot=2)
```

```
#with both level 1 and 2 exposure
data3<-data.org(x=cbind(sim.211$x,sim.111$x), m=sim.211$m,
  f20ky=list(2,c("x","x^3")), f01km1=list(matrix(c(2,1),1),"sqrt(x)+3"),
  f01km2=list(matrix(c(1,1),1),c("x^1.2","x^2.3")), level=sim.211$level)
temp3.boot<-boot.mlma(y=sim.211$y, data1=data3,boot=2)
```

Description

To transform variables and generate data sets for mediation analysis.

Usage

```
data.org(x, m, levely = 1, y = NULL, levelx = NULL, xref =
        NULL, l1 = NULL, l2 = NULL, c1 = NULL, c1r = NULL, c2
        = NULL, c2r = NULL, f01y = NULL, f10y = NULL, f02ky =
        NULL, f20ky = NULL, f01km1 = NULL, f01km2 = NULL,
        f10km = NULL, level = 1:nrow(as.matrix(x)), weight =
        NULL)
```

Arguments

x	the data frame of exposure variable(s). If there are multiple exposures, a categorical exposure should be binarized with the reference group coded as 0.
m	the data frame of all mediators. The program will identify the levels and types of each mediator if not specified by l1, l2, c1, or c2. A mediator is identified as categorical if the mediator is a factor, a character, or has only two unique values. Note: the name for one mediator should NOT be the subset of the name of another mediator.
levely	the level of y (1 or 2), 1 by default. If it is NULL, levely will be decided automatically by y.
y	only needed if levely is not given.
levelx	the vector of levels of every column of x (1 or 2). If it is not given, levelx will be decided automatically. If there is only level 1 exposure, but there are level 2 mediator(s), the level 2 exposure will be created by aggregate all the level 1 exposure(s) to level 2.
xref	the reference group of x if it is a single binary variable. By default it will be the first level of x.
l1	the column numbers of level 1 continuous mediators in m or the list of names of the level 1 continuous mediators.
l2	the column numbers of level 2 continuous mediators in m or the list of names of the level 2 continuous mediators.
c1	the column numbers of level 1 categorical mediators in m or the list of names of the level 1 categorical mediators.
c1r	the reference groups of categorical mediators specified by c1.
c2	the column numbers of level 2 categorical mediators in m or the list of names of the level 2 categorical mediators.
c2r	the reference groups of categorical mediators specified by c2.

- f01y the transformation function expressions on level 2 exposures (x.jm) in explaining y (eg, list(1,c("x^2","log(x)"))). The first item lists column numbers/variable names of the level 2 exposures in x, which needs to be transformed. By that order, each of the rest items of f01y list the transformation functional expressions for each exposure. The exposures not specified in the list will not be transformed in any way.
- f10y the transformation function expressions on level 1 exposure (xijm) in explaining y. (eg, list(2,c("x^2","log(x)"))). The first item lists column numbers/variable names of the level 1 exposures in x, which needs to be transformed. By that order, each of the rest items of f10y list the transformation functional expressions for each exposure. The exposures not specified in the list will not be transformed in any way.
- f02ky the transformation-function-expression list on level 2 mediators (m.jk) in explaining y (eg, list(2:3,c("log(x)","sqrt(x)", "2*x"))). The first item lists column numbers/variable names of the level 2 mediators in m, which needs to be transformed. By that order, each of the rest items of f02ky list the transformation functional expressions for each mediator. The mediators not specified in the list will not be transformed in any way.
- f20ky the transformation-function-expression list on level 1 mediators (mijk-m.jk) in explaining y. The first item lists column numbers/variable names of the level 1 mediators in m, which needs to be transformed. By that order, each of the rest items of f20ky list the transformation functional expressions for each mediator. The mediators not specified in the list will not be transformed in any way.
- f01km1 the transformation-function-expression list on level 2 predictor (x.jm) in explaining the level 1 mediators. The first item is a matrix with two columns, the first column is the column numbers of the level 1 mediators in m, which should be explained by the transformed predictor(s). The second column indicates the column number of the exposure in x that will be transformed to explain the mediator identified by the 1st column of the same row. By the order of the rows of the first item, each of the rest items of f01km1 lists the transformation functional expressions for the level 2 exposure (identified by column 2) in explaining each mediator (identified by column 1). The mediators not specified in the list will be explained by the original format of the level 2 exposures. e.g. list(matrix(c(1,2,1,1),2,2), "x^2","x^2") means $x_{[,1]}^2$ is used to explain both $m_{[,1]}$ and $m_{[,2]}$.
- f01km2 the transformation-function-expression list on level 2 predictor (x.jm) in explaining the level 2 mediators. The first item is a matrix with two columns, the first column is the column numbers of the level 2 mediators in m, which should be explained by the transformed predictor(s). The second column indicates the column number of the exposure in x that will be transformed to explain the mediator identified by the 1st column of the same row. By the order of the rows of the first item, each of the rest items of f01km2 lists the transformation functional expressions for the level 2 exposure (identified by column 2) in explaining each mediator (identified by column 1). The mediators not specified in the list will be explained by the original format of all level 2 exposures.
- f10km the transformation-function-expression list on level 1 predictor (xijm) in explaining the level 1 mediators. The first item is a matrix with two columns,

the first column is the column numbers of the level 1 mediators in m , which should be explained by the transformed level 1 exposure(s). The second column indicates the column number of the exposure in x that will be transformed to explain the mediator identified by the 1st column of the same row. By the order of the rows of the first item, each of the rest items of `f10km` lists the transformation functional expressions for the level 1 exposure (identified by column 2) in explaining each mediator (identified by column 1). The mediators not specified in the list will be explained by the original format of all level 1 exposures.

`level` a vector that record the group number for each observation.
`weight` the weight of cases in groups.

Details

The arguments starting with "f" are used to specify the transformation functions of the predictor or mediators in explaining y , or the transformation functions of the predictor in explaining the mediators. If the name of the argument includes a "k", the transformation is on the mediators. If the names of the arguments end with "y", the transformation is to explain the outcome. Otherwise, the transformation is on x to predict mediators (the argument ends with "m1" or "m" (for level 1 mediator), or "m2" (for level 2 mediator)). The functions corresponds to the functions in the following multilevel additive models, reading as f+subscript+superscript. For example, `f01y` specifies f_{01}^Y .

$$Y_{ij} = u_{0j}^Y(X_{.j}, \mathbf{M}_{.j}, \mathbf{Z}_{.j}) + \beta_{10}^Y T \mathbf{f}_{10}^Y(X_{ij} - X_{.j}) + \sum_{k=1}^K \beta_{20k}^Y T \mathbf{f}_{20k}^Y(M_{ijk} - M_{.jk}) + \beta_{30}^Y T (\mathbf{Z}_{ij} - \mathbf{Z}_{.j}) + r_{ij}^Y,$$

where

$$u_{0j}^Y(X_{.j}, \mathbf{M}_{.j}, \mathbf{Z}_{.j}) = c_{00}^Y + \beta_{01}^Y T \mathbf{f}_{01}^Y(X_{.j}) + \sum_{k=1}^K \beta_{02k}^Y T \mathbf{f}_{02k}^Y(M_{.jk}) + \beta_{03}^Y T \mathbf{Z}_{.j} + r_{0j}^Y.$$

For $k = 1, \dots, K$,

$$M_{.jk} = u_{0jk}^M(X_{.j}) + \beta_{10k}^M T \mathbf{f}_{10k}^M(X_{ij} - X_{.j}) + r_{ijk}^M,$$

$$u_{0jk}^M(X_{.j}) = c_{00k}^M + \beta_{01k}^M T \mathbf{f}_{01k}^{M1}(X_{.j}) + r_{0jk}^M.$$

If for some k , M_k is level 2 variable,

$$M_{.jk} = c_{00k}^M + \beta_{01k}^M T \mathbf{f}_{01k}^{M2}(X_{.j}) + r_{0jk}^M.$$

The transformation function can be any function that is differentiable by the function `deriv()`, or the `ifelse` function with those functions. The transformation function can also be the `ns()` and `bs()` functions for natural and b spline basis.

Value

The function returns a list with transformed and organized data with the following items:

`x1` the level 1 and 2 transformed predictor variable matrix in explaining y (eg, `f01y(x,j)` & `f10y(xij)`).

<code>lx</code>	a matrix with <code>ncol(x)</code> rows and three columns. The <i>i</i> th row is for the <i>j</i> th column of <i>x</i> . The first column of the <i>i</i> th row gives the level (1 or 2) of the <i>i</i> th column of <i>x</i> . <code>lx[i,2]:lx[i,3]</code> gives the column numbers of transformed <i>i</i> th <i>x</i> in <i>x1</i> .
<code>m1y</code>	the level 1 mediator matrix in explaining <i>y</i> (eg, <code>f20ky(mijk-m.jk)</code> & <code>mijk</code> or binarized <code>mijk</code> for categorical mediators).
<code>m1</code>	a list where the first item identify column numbers of level 1 mediators in <i>m</i> (ie, <code>c(11,c1)</code>). For every mediator identified by <code>m1[[1]]</code> and by that order, each of the rest item identify the column number(s) in <code>m1y</code> the (transformed) value(s) of the mediator in explaining <i>y</i> .
<code>m2y</code>	the level 2 mediator (original or aggregated) matrix in explaining <i>y</i> (eg, <code>f02ky(m.jk)</code> & <code>m.jk</code>).
<code>m2</code>	a list where the first item identify column numbers of level 2 mediators in <i>m</i> (i.e., <code>c(12,c2)</code>). For every mediator identified by <code>m2[[1]]</code> and by that order, each of the rest item identify the column number(s) in <code>m2y</code> the (transformed) value(s) of the mediator in explaining <i>y</i> .
<code>xm1</code>	the (transformed) level 1 and level 2 predictor(s) in explaining level 1 mediators.
<code>fm11</code>	a list where the first item identify column numbers of level 1 mediators in <i>m</i> . For every mediator identified by <code>fm11[[1]]</code> and by that order, each of the rest item identify the column number(s) in <code>xm1</code> the (transformed) level 1 predictor(s) in explaining the mediator.
<code>fm12</code>	a list where the first item identify column numbers of level 1 mediators in <i>m</i> . For every mediator identified by <code>fm12[[1]]</code> and by that order, each of the rest item identify the column number(s) in <code>xm1</code> the (transformed/aggregated) level 2 predictor(s) in explaining the mediator.
<code>m.2</code>	a matrix of level 2 mediators (one row for each group).
<code>xm2</code>	the (transformed/aggregated) level 2 predictor(s) in explaining level 2 mediators (one row for each group).
<code>fm22</code>	a list where the first item identify column numbers of level 2 mediators in <i>m</i> . For every mediator identified by <code>fm22[[1]]</code> and by that order, each of the rest item identify the column number(s) in <code>xm2</code> the (transformed) level 2 predictor(s) in explaining the mediator.
<code>x1.der, m2y.der, m1y.der, xm2.der, xm1.der</code>	the derivative of <code>x1</code> , <code>m2y</code> , <code>m1y</code> , <code>xm2</code> , and <code>xm1</code> respectively.
<code>f01km1.2</code>	the first item is <code>f01km1[[1]]</code> . The rest are the column numbers of <code>f01km1[[i]]</code> in <code>xm1</code> .
<code>f01km2.2</code>	the first item is <code>f01km2[[1]]</code> . The rest are the column numbers of <code>f01km2[[i]]</code> in <code>xm2</code> .
<code>f10km.2</code>	the first item is <code>f10km[[1]]</code> . The rest are the column numbers of <code>f10km[[i]]</code> in <code>xm1</code> .
<code>binx</code>	the <i>i</i> th item of <code>binx</code> is TRUE if the <i>i</i> th predictor is binary, otherwise is FALSE.
<code>parameter</code>	The list of all arguments.

```

joint.effect

Find the joint effect of a list of mediators.

Description

This function provides the inference information (estimation, standard deviation, etc.) for the joint and relative effect of a list of mediators.

Usage

```

joint.effect(object, var.list, digits=4, ..., alpha=0.05)
## S3 method for class 'joint.effect'
print(x, ...)

```

Arguments

object	an "boot.mlma" object.
x	an "joint.effect" object from the joint.effect function.
var.list	a list of mediators whose joint effects are of interest.
...	arguments to be passed to methods.
alpha	the significance level at which to draw the confidence bands.
digits	number of digits to be printed.

Author(s)

Qingzhao Yu (qyu@lsuhsc.edu), Bin Li (bli@lsu.edu).

Examples

```
data(sim.111)
data(sim.211)

               f20ky=list(2,c("x","x^3")), f01km1=list(matrix(c(2,1),1),"sqrt(x)+3"),
               f01km2=list(matrix(c(1,1),1),c("x^1.2","x^2.3")), level=sim.211$level)
temp3.boot<-boot.mlma(y=sim.211$y, data1=data3,boot=2)
joint.effect(temp3.boot, var.list=c("m.4"))
```

mlma

Multilevel Mediation Analysis

Description

The function transforms the data set and does multilevel mediation analysis. The total, direct, and indirect effects will be returned as the results.

Usage

```
mlma(y, data1=NULL, x=data1$parameter$x, m=data1$parameter$m,
     yref=NULL, xref=NULL, levelx=data1$parameter$levelx,
     levely=data1$parameter$levely,
     l1=data1$parameter$l1,l2=data1$parameter$l2,
     c1=data1$parameter$c1, #levelx is the level of x
     c1r=data1$parameter$c1r, c2=data1$parameter$c2,
     c2r=data1$parameter$c2r,level=data1$parameter$level,
     weight=rep(1, nrow(data.frame(x))),
     random="(1|level)", random.m1=NULL,intercept=TRUE,
     family1=NULL, familym=vector("list",ncol(m)),
     covariates=NULL, cy1=NULL, cy2=NULL, cm=NULL,joint=NULL,
     f01y=data1$parameter$f01y,f10y=data1$parameter$f10y,
     f02ky=data1$parameter$f02ky, f20ky=data1$parameter$f20ky,
     f01km1=data1$parameter$f01km1,f01km2=data1$parameter$f01km2,
     f10km=data1$parameter$f10km, data2=NULL, x.new=NULL,
     m.new=NULL, level.new=level, weight.new=NULL,
     covariates.new=covariates,cov.mat=FALSE)
```

Arguments

y	the vector of the outcome variable.
data1	The transformed and organized data set from data.org. If the data set has not been organized, leave data1=NULL (by default), and set the transformation functions (f arguments). Otherwise, set data1 as the output from the data.org function and do not include the arguments starting with fs.
x	the vector of the predictive variable.

<code>m</code>	the mediators. The program will identify the levels and types of each mediator if not specified by <code>l1</code> , <code>l2</code> , <code>c1</code> , or <code>c2</code> . A mediator is identified as categorical if the mediator is a factor, a character, or has only two unique values.
<code>yref</code>	the reference group of <code>y</code> if it is binary. By default it will be the first level of <code>y</code> .
<code>xref</code>	the reference group of <code>x</code> if it is binary. By default it will be the first level of <code>x</code> .
<code>levelx</code>	the level of <code>x</code> (1 or 2). If it is not given, <code>levelx</code> will be decided by <code>x</code> .
<code>levely</code>	the level of <code>y</code> (1 or 2). If it is not given, <code>levely</code> will be decided by <code>y</code> .
<code>l1</code>	the column numbers of level 1 continuous mediators in <code>m</code> or the list of names of the level 1 continuous mediators.
<code>l2</code>	the column numbers of level 2 continuous mediators in <code>m</code> or the list of names of the level 2 continuous mediators.
<code>c1</code>	the column numbers of level 1 categorical mediators in <code>m</code> or the list of names of the level 1 categorical mediators.
<code>c1r</code>	the reference groups of categorical mediators specified by <code>c1</code> .
<code>c2</code>	the column numbers of level 2 categorical mediators in <code>m</code> or the list of names of the level 2 categorical mediators.
<code>c2r</code>	the reference groups of categorical mediators specified by <code>c2</code> .
<code>level</code>	a vector that record the group number for each observation.
<code>weight</code>	the weight of cases in groups.
<code>random</code>	the random effect part for the full model. <code>random = "(1 level)"</code> by default.
<code>random.m1</code>	the random effect part for model explaining the mediators. If not null, 1st item of <code>random.m1</code> is the list of level 1 mediators, following items are the random item of the same order. All other random effects are <code>random = "(1 level)"</code> if not specified here.
<code>intercept</code>	True if fit an intercept to models, by default.
<code>covariates</code>	the covariates matrix to explain the outcome, <code>y</code> , and/or the mediators, <code>m</code> .
<code>family1</code>	the glm family for the response variable <code>y</code> . If it is null, will be binomial with logic link for binary <code>y</code> and gaussian with identity link for continuous <code>y</code> .
<code>familym</code>	a list of length <code>ncol(m)</code> , each item gives the glm family for the corresponding column of <code>m</code> . If an item is null, the family will be binomial with logic link for binary <code>m</code> and gaussian with identity link for continuous <code>m</code> .
<code>cy1</code>	the column numbers of covariates that are level 1 and used to explain <code>y</code> .
<code>cy2</code>	the column numbers of covariates that are level 2 and used to explain <code>y</code> .
<code>cm</code>	the column numbers of covariates that are used to explain <code>m</code> . <code>cm[[1]]</code> gives the mediators (in <code>l1</code> , <code>c1</code> , <code>l2</code> , or <code>c2</code>) that can be partially explained by covariates. Each of the rest items of the <code>cm</code> list shows the column number(s) in covariates that should be used to explain each mediator listed in <code>cm[[1]]</code> and by that order.
<code>joint</code>	the list of group(s) of mediators whose joint mediation effect is of interests. <code>joint[[1]]</code> list the levels of mediators in each group and by the order of the list. Note that if any mediator in the group is of level 2, the level of the group should be 2.

f01y, f10y, f02ky, f20ky, f01km1, f01km2, f10km	the transformation functions as describe in the function " data.org ". Need these arguments only when org.data=T.
x.new, m.new, level.new, weight.new, covariates.new	the settings that we want to make inferences on the mediation effects.
data2	The transformed and organized data set from data.org on the set of new x.new and m.new etc.. If the data set has not been organized, leave data2=NULL (by default).
cov.mat	If true, save the estimated variances for mediation effects by normal assumption.

Details

The multilevel mediation is based on the following linear multilevel additive models:

$$Y_{ij} = u_{0j}^Y(X_{.j}, \mathbf{M}_{.j}, \mathbf{Z}_{.j}) + \beta_{10}^Y \mathbf{f}_{10}^Y(X_{ij} - X_{.j}) + \sum_{k=1}^K \beta_{20k}^Y \mathbf{f}_{20k}^Y(M_{ijk} - M_{.jk}) + \beta_{30}^Y \mathbf{Z}_{.j} + r_{ij}^Y,$$

where

$$u_{0j}^Y(X_{.j}, \mathbf{M}_{.j}, \mathbf{Z}_{.j}) = c_{00}^Y + \beta_{01}^Y \mathbf{f}_{01}^Y(X_{.j}) + \sum_{k=1}^K \beta_{02k}^Y \mathbf{f}_{02k}^Y(M_{.jk}) + \beta_{03}^Y \mathbf{Z}_{.j} + r_{0j}^Y.$$

For $k = 1, \dots, K$,

$$M_{.jk} = u_{0jk}^M(X_{.j}) + \beta_{10k}^M \mathbf{f}_{10k}^M(X_{ij} - X_{.j}) + r_{ijk}^M,$$

$$u_{0jk}^M(X_{.j}) = c_{00k}^M + \beta_{01k}^M \mathbf{f}_{01k}^{M1}(X_{.j}) + r_{0jk}^M.$$

If for some k , M_k is level 2 variable,

$$M_{.jk} = c_{00k}^M + \beta_{01k}^M \mathbf{f}_{01k}^{M2}(X_{.j}) + r_{0jk}^M.$$

Note that in the models, $\mathbf{f}(\cdot) = (f_1(\cdot), f_2(\cdot), \dots, f_l(\cdot))^T$ is a set of l transformation functions on \cdot , with the corresponding linear coefficients vector $\boldsymbol{\beta} = (\beta_1, \beta_2, \dots, \beta_l)^T$. \mathbf{f} and l are known for model fitting. l may be different with \mathbf{f} of different sub- and super-scripts.

Value

A "mlma" mode list will be returned with the following items:

de1	direct effect(s) of level 1 exposure(s). de1 is a matrix of dimension n by $nx1$, where n is the number of observations, and $nx1$ is the number of level 1 exposures.
de2	direct effect(s) of level 2 exposure(s). de2 is a matrix of dimension $n2$ by $nx2$, where $n2$ is the number of unique levels, and $nx2$ is the number of level 2 exposures.
ade1	average direct effect(s) of level 1 exposure(s). ade1 is a vector of length $nx1$.
ade2	average direct effect(s) of level 2 exposure(s). ade2 is a vector of length $nx2$.

te1	total effect of each level 1 exposure. te1 is a matrix of dimension n by $nx1$, where n is the number of observations, and $nx1$ is the number of level 1 exposures.
te2	total effect of each level 2 exposure. te2 is a matrix of dimension $n2$ by $nx2$, where $n2$ is the number of unique levels, and $nx2$ is the number of level 2 exposures.
ate1	average total effect(s) of level 1 exposure(s). ate1 is a vector of length $nx1$.
ate2	average total effect(s) of level 2 exposure(s). ate2 is a vector of length $nx2$.
ie1	level 1 indirect effect from level 1 exposure(s) to level 1 mediator(s) on the outcome. ie1 is an array of dimension $(n, nm1, nx1)$, where $nm1$ is the number of level 1 mediators.
ie2	level 2 indirect effect from level 2 exposure(s) to level 2 mediator(s) on the outcome. ie2 is an array of dimension $(n2, nm2, nx2)$, where $nm2$ is the number of level 2 mediators.
ie12	level 2 indirect effect from level 2 exposure(s) to level 1 mediator(s) on the outcome. ie12 is an array of dimension $(n2, nm1, nx2)$.
aie1	level 1 average indirect effect from level 1 exposure(s) to level 1 mediator(s) on the outcome. aie1 is a matrix of dimension $(nm1, nx1)$.
aie2	level 2 average indirect effect from level 2 exposure(s) to level 2 mediator(s) on the outcome. aie2 is a matrix of dimension $(nm2, nx2)$.
aie12	level 2 average indirect effect from level 2 exposure(s) to level 1 mediator(s) on the outcome. aie12 is a matrix of dimension $(nm1, nx2)$.
je1	joint level 1 indirect effect from level 1 exposure(s) to joint level 1 mediators on the outcome. je1 is an array of dimension $(n, nj1, nx1)$, where $nj1$ is the number of groups of level 1 mediators.
je2	joint level 2 indirect effect from level 2 exposure(s) to joint level 2 mediators on the outcome. je2 is an array of dimension $(n2, nj2, nx2)$, where $nj2$ is the number of groups of level 2 mediators.
je12	joint level 2 indirect effect from level 2 exposure(s) to joint level 1 mediators on the outcome. je12 is an array of dimension $(n2, nj1, nx2)$.
aje1	average joint level 1 indirect effect from level 1 exposure(s) to joint level 1 mediators on the outcome. aje1 is a matrix of dimension $(nj1, nx1)$.
aje2	average joint level 2 indirect effect from level 2 exposure(s) to joint level 2 mediators on the outcome. aje2 is a matrix of dimension $(nj2, nx2)$, where $nj2$ is the number of groups of level 2 mediators.
aje12	average joint level 2 indirect effect from level 2 exposure(s) to joint level 1 mediators on the outcome. aje12 is a matrix of dimension $(nj1, nx2)$.
f1	the overall multilevel model.
fm1	a list, where the first item identifies the level 1 mediators, and in that order, the following items give the prediction functions of the mediators.
fm2	a list, where the first item identifies the level 2 mediators, and in that order, the following items give the prediction functions of the mediators.
ie1_1, ie1_2, ie1_3, ie2_1, ie2_2, ie2_3	the first, second and third part of the corresponding indirect effects.

x	the matrix of the new exposure variable(s) (x.new).
x.j	the vector of the aggregated x at the higher level by the order of unique(level.new[!is.na(level.new)]).
data1	The results from data.org on the original data (x, m, etc.).
data2	The results from data.org on the new data (x.new, m.new, etc.).

Author(s)

Qingzhao Yu (qyu@lsuhsc.edu), Bin Li (bli@lsu.edu).

Examples

```
#with a level 1 exposure
data(sim.111)
data2<-data.org(sim.111$x, m=sim.111$m,
  f10y=list(1,c("x^2","sqrt(x+6)")),
  f20ky=list(2,c("x","x^3")),
  f10km=list(matrix(c(2,1),1),"log(x+2)"), level=sim.111$level)
temp2<-mlma(y=sim.111$y, data1=data2)

#can also do the above analysis using the following code
temp2<-mlma(y=sim.111$y, x=sim.111$x, m=sim.111$m,
  f10y=list(1,c("x^2","sqrt(x+6)")),
  f20ky=list(2,c("x","x^3")),
  f10km=list(matrix(c(2,1),1),"log(x+2)"), level=sim.111$level)

#with a level 2 exposure
data(sim.211)

  f01y=list(1,c("x","log(x^2)")), f02ky=list(1,c("x","x^2")),
  f20ky=list(2,c("x","x^3")), f01km2=list(matrix(c(1,1),1),c("x^1.2","x^2.3")),
  f01km1=list(matrix(c(2,1),1),"sqrt(x)+3"), level=sim.211$level)
temp1<-mlma(y=sim.211$y, data1)

#with both level 1 and 2 exposure
data3<-data.org(x=cbind(sim.211$x,sim.111$x), m=sim.211$m,
  f01y=list(1,c("x","log(x^2)")), f02ky=list(1,c("x","x^2")),
  f20ky=list(2,c("x","x^3")), f01km1=list(matrix(c(2,1),1),"sqrt(x)+3"),
  f01km2=list(matrix(c(1,1),1),c("x^1.2","x^2.3")), level=sim.211$level)
temp3<-mlma(y=sim.211$y, data3)
```

plot.mlma

Plot "mlma" Object

Description

Plot the overall mediation effect or decomposed indirect effect from the selected mediator.

Usage

```
## S3 method for class 'mlma'
plot(x, ..., var=NULL, cate=FALSE,
      w2=rep(1, nrow(as.matrix(object$de2))))
```

Arguments

x	an "mlma" object.
...	arguments to be passed to methods.
var	the name of the mediator that is to be plotted. If var is NULL, plot the relative mediation effects of all mediators.
cate	an indicator of whether the variable is categorical or not.
w2	the weight for observations at level 2, which should be the same order as unique(level[!is.na(level)]). The default is rep(1, length(object\$de2)).

Details

Plot the relative effects of direct effects and indirect effects of mediators at level 1 (if levelx=1) and level 2 respectively if var=NULL. Otherwise, plot the indirect effect of var, the estimated differential effect of the predictor on var, and the predicted relationship between y and var at individual level and/or (aggregated) group level.

```

plot.mlma.boot *Plot the "mlma.boot" Object*

Description

For the mediator identified by var, the function draws the level 1 and/or (aggregated) level 2 indirect effects versus the predictor and the confidence bands at alpha significance level. If var is NULL, draw the relative mediation effects with confidence intervals.

Usage

```

## S3 method for class 'mlma.boot'
plot(x,..., var=NULL, alpha=0.05,quant=FALSE, plot.it=x$plot.it)

```

Arguments

x	an "mlma" object.
...	arguments to be passed to methods.
var	the name of the mediator that is to be plotted.
alpha	the significance level at which to draw the confidence bands.
quant	if true, confidence interval is calculated using quantil when plot the relative effects. By default, the CIs are calculated using normal approximation. This argument does nothing for the CIs calculated when var is not null.
plot.it	If true, will plot confidence intervals.

Examples

```

data(sim.211)
data1<-data.org(x=ifelse(sim.211$x>2.2,1,0), m=sim.211$m,
               f02ky=list(1,c("x","x^2")),
               f20ky=list(2,c("x","x^3")), f01km2=list(matrix(c(1,1),1),c("x^1.2","x^2.3")),
               f01km1=list(matrix(c(2,1),1),"sqrt(x)+3"),level=sim.211$level)
temp1.boot<-boot.mlma(y=sim.211$y, data1=data1,boot=2)
plot(temp1.boot)
plot(temp1.boot,var="m.1")
plot(temp1.boot,var="m.3")
#plot(temp1.boot,var="m.4")

```

print.mlma

Print "mlma" Object

Description

print the level 1 and level 2 mediation effects from the object.

Usage

```

## S3 method for class 'mlma'
print(x,...,w2=rep(1,nrow(as.matrix(object$de2))),digits=2)

```

Arguments

x	an "mlma" object.
...	arguments to be passed to methods.
w2	the weight for observations at level 2, which should be the same order as unique(level[!is.na(level)]). The default is rep(1,length(object\$de2)).
digits	the number of digits to print.

Author(s)

Qingzhao Yu (qyu@lsuhsc.edu), Bin Li (bli@lsu.edu).

Examples

```

data(sim.111)
#with a level 1 exposure
data(sim.111)
data2<-data.org(sim.111$x, m=sim.111$m,
               f10y=list(1,c("x^2","sqrt(x+6)")),
               f20ky=list(2,c("x","x^3")),
               f10km=list(matrix(c(2,1),1),"log(x+2)", level=sim.111$level)
temp2<-mlma(y=sim.111$y, data1=data2)
print(temp2)

```

```

#with a level 2 exposure
data(sim.211)
data1<-data.org(x=sim.211$x, m=sim.211$m,
  f01y=list(1,c("x","log(x^2)")), f02ky=list(1,c("x","x^2")),
  f20ky=list(2,c("x","x^3")), f01km2=list(matrix(c(1,1),1),c("x^1.2","x^2.3")),
  f01km1=list(matrix(c(2,1),1),"sqrt(x)+3"),level=sim.211$level)
temp1<-mlma(y=sim.211$y, data1)
temp1

#with both level 1 and 2 exposure
data3<-data.org(x=cbind(sim.211$x,sim.111$x), m=sim.211$m,
  f01y=list(1,c("x","log(x^2)")), f02ky=list(1,c("x","x^2")),
  f20ky=list(2,c("x","x^3")), f01km1=list(matrix(c(2,1),1),"sqrt(x)+3"),
  f01km2=list(matrix(c(1,1),1),c("x^1.2","x^2.3")), level=sim.211$level)
temp3<-mlma(y=sim.211$y, data3)
temp3

```

```
print.mlma.boot      Print "mlma.boot" Object
```

Description

print the level 1 and level 2 mediation effects from the object.

Usage

```
## S3 method for class 'mlma.boot'
print(x,...)
```

Arguments

```
x          an "mlma.boot" object.
...        other arguments
```

Author(s)

Qingzhao Yu (qyu@lsuhsc.edu), Bin Li (bli@lsu.edu).

Examples

```

data(sim.111)
data2<-data.org(ifelse(sim.111$x>1.9,1,0), m=sim.111$m,
  f10y=list(1,c("x^2","sqrt(x+6)")),
  f20ky=list(2,c("x","x^3")),
  f10km=list(matrix(c(2,1),1),"log(x+2)", level=sim.111$level)
temp2.boot<-boot.mlma(y=sim.111$y, data1=data2,boot=2)

print(temp2.boot)

```

sim.111	<i>Simulated 1-1-1 Data set</i>
---------	---------------------------------

Description

A simulated data set, where both predictor and outcome are level 1 variables.

Usage

```
data("sim.111")
```

Format

The data set contains 10 groups, each group has 30 observations. The format is list, where there are four elements:

x: the level 1 continuous predictor.

y: the level 1 continuous outcome.

m: the matrix of mediators, where there are three level 1 mediators, where m.2 and m.3 are continuous, and m.4 is categorical with 3 levels.

level: the group level for each observation.

Examples

```
data(sim.111)
```

sim.211	<i>Simulated 2-1-1 Data</i>
---------	-----------------------------

Description

A simulated data set, where the predictor is a level 2 and the outcome is a level 1 variable.

Usage

```
data("sim.211")
```

Format

The data set contains 10 groups, each group has 30 observations. The format is list, where there are four elements:

x: the level 1 continuous predictor.

y: the level 1 continuous outcome.

m: the matrix of mediators, where there are one level 2 mediator, m.1, and two level 1 mediators, m.3 and m.4. m.4 is categorical with 3 levels.

level: the group level for each observation.

Examples

```
data(sim.211)
```

```
summary.mlma
```

Summary of "mlma" Object

Description

This function provides ANOVA tests on the predictors and mediators in the full model and on the predictors for models in explaining each mediators.

Usage

```
## S3 method for class 'mlma'
summary(object,...,type="III")
## S3 method for class 'summary.mlma'
print(x, ...)
```

Arguments

object	an "mlma" object.
x	a summary.mlma.boot object created initially call to summary.mlma.boot.
...	arguments to be passed to methods.
type	type of test, "II", "III", 2, or 3.

Author(s)

Qingzhao Yu (qyu@lsuhsc.edu), Bin Li (bli@lsu.edu).

Examples

```
data(sim.111)
data2<-data.org(ifelse(sim.111$x>1.9,1,0), m=sim.111$m,
                f10y=list(1,c("x^2","sqrt(x+6)")),
                f20ky=list(2,c("x","x^3")),
                f10km=list(matrix(c(2,1),1),"log(x+2)"), level=sim.111$level)
temp2<-mlma(y=sim.111$y, data1=data2)
summary(temp2)
```

summary.mlma.boot *Summary of "mlma.boot" Object*

Description

This function provide summary statistics for all mediation effects.

Usage

```
## S3 method for class 'mlma.boot'  
summary(object, ..., alpha = 0.05, RE=FALSE, digits=4)  
## S3 method for class 'summary.mlma.boot'  
print(x, ..., digits=x$digits)
```

Arguments

object	an "mlma" object.
x	a summary.mlma.boot object created initially call to summary.mlma.boot.
...	arguments to be passed to methods.
alpha	the significance level at which to draw the confidence bands.
RE	if true, print the relative effects, otherwise show the mediation effects.
digits	the number of digits to print.

Author(s)

Qingzhao Yu (qyu@lsuhsc.edu), Bin Li (bli@lsu.edu).

Examples

```
data(sim.111)  
data(sim.211)  
data3<-data.org(x=cbind(ifelse(sim.211$x>1.9,1,0),sim.111$x), m=sim.211$m,  
                  f20ky=list(2,c("x","x^3")), f01km1=list(matrix(c(2,1),1),"sqrt(x)+3"),  
                  f01km2=list(matrix(c(1,1),1),c("x^1.2","x^2.3")), level=sim.211$level)  
temp3.boot<-boot.mlma(y=sim.211$y, data1=data3,boot=2)  
summary(temp3.boot, digits=2)  
summary(temp3.boot, RE=TRUE)
```
